Attention is up.
What decision follows?

SYNTHETIC SCENARIO / NOT CLIENT DATA / REVIEW DRAFT

01 / BUSINESS QUESTION

A fictional commerce campaign gains attention without gaining purchases. What should an analyst investigate before recommending a change? Two illustrative, equal 14-day periods; USD throughout.

02 / OBSERVED FIXTURE

Engaged sessions: **2,000 to 3,300 (+65%)**. Sessions: 5,000 to 7,500. Purchases: **100 to 100**. Revenue: **$8,000 to $8,000**. Observed session conversion: 2.00% to 1.33%. These are invented counts, not client results.

03 / MEASUREMENT INTEGRITY

120 raw purchase firings include 20 duplicates, leaving 100 unique orders. Deduplication fixes a counting discrepancy; it does not explain flat revenue. If tracking is broken, pause conversion and channel conclusions.

04 / RECOMMENDED ACTION

Reconcile measurement before changing spend. Compare transaction IDs, values, currency and refunds with the order ledger. Inspect consent-aware delivery and missing campaign labels. Rebaseline after the checks, then preregister a controlled test with purchase and revenue guardrails.

05 / ASSUMPTIONS AND BUSINESS RELEVANCE

Default missingness assumption: 0%; 100 modelled purchases, not recovered sales. At an assumed $1,000 delivery cost and $40 contribution per incremental order, break-even needs **25 incremental orders**. This is a hurdle, not a forecast. The aim is to reduce the risk of funding the wrong fix; no uplift or causality is established.

06 / ENGINEERING EVIDENCE

Exclamation AI is the separate technical source: ordered SQL/Python analysis, documented Google reconciliation and measurement receipts. Historical Google work is separate from this synthetic challenge. Live model quality and BigQuery SDK transport remain unverified.
Inspect verification and limitations at the audited source revision.
